Artículo original

Resumen

Introducción: La relación entre la adherencia a la dieta mediterránea y la grasa central en nadadores adolescentes está poco estudiada. La grasa es un componente interesante en natación debido a su relación con la horizontal flotabilidad horizontal y la velocidad de nado. Una acumulación de grasa abdominal se considera un factor negativo para la salud y el rendimiento deportivo. Este estudio, que se llevó a cabo está destinado a investigar los índices de adherencia a la dieta mediterránea y su relación con algunos índices de grasa central en nadadores ado cas de natación. Para ello, se realizaron mediciones antropométricas y se completó un cuestionario KIDMED.

Material y método: Se llevó a cabo un estudio transversal con 74 nadadores adolescentes (chicos n= 34, 14,5 ± 1,3 y.o.; chicas n= 40, 13,6 ± 1,2 y.o.). Se valoró la adherencia a la dieta mediterránea a través del índice KIDMED. Los nadadores fueron medida a a la misma hora del día, antes de la sesión de entrenamiento. Los resultados se compararon con los de otros estudios similares. El análisis estadístico se realizó con el programa SPSS 19.0.

Resultados: Los nadadores mostraron un índice KIDMED promedio de 8,09 ± 1,5 para los chicos y 7,23 ± 2,2 para las chicas. No se encontró una relación significativa entre la adherencia a la dieta mediterránea y los índices de grasa central. Sin embargo, se observó una tendencia hacia una mayor adherencia en los chicos.

Conclusiones: Independientemente del grado de adherencia a la dieta mediterránea, la actividad nata toria de los nadadores adolescentes permite mantener los índices de grasa central en valores saludables. A pesar de no encontramos asociación entre la adherencia a la dieta mediterránea y los índices de grasa central, existen razones de salud para mejorar los hábitos alimenticios saludables en nadadores adolescentes de natación.

Palabras clave:
Introduction

Diet has an important role in the health, growth, performance, and recovery of swimmers. An imbalanced diet has been described in young swimmers\textsuperscript{1,2}. The Mediterranean Diet (MD) has long been reported to have a large number of benefits such as the prevention of non-communicable diseases\textsuperscript{3}, a lower risk of mortality\textsuperscript{4}, and a lower incidence of many types of cancers\textsuperscript{5}. It could reduce central obesity and the associated chronic disease risks\textsuperscript{6}. The MD is considered a healthy diet, and it is in line with general recommendations on nutrition for athletic performance. A recent review has provided data on the association between adherence to the MD and body composition\textsuperscript{7}. However, in adolescents, there is still an unclear correlation between adherence to the MD, physical activity, and body composition\textsuperscript{8-11}. Although, the MD can be considered one of the best studied dietary patterns in the world, the data on adolescent athletes and adherence to the MD is sparse\textsuperscript{12,13}.

The swimmers have some "typical" anthropometric characteristics. They have long limbs and their musculoskeletal components are important in sport performance. In particular, the fat component is a paradoxical component in swimming, because of its relationship to the floatation and speed during the performance\textsuperscript{14}. Previous studies have shown that the swimmers could accumulate central fat during short break from swimming activity\textsuperscript{14,15}. Accumulation of central fat is an important risk factor in the development of insulin resistance, diabetes, metabolic syndrome, and cardiovascular diseases\textsuperscript{16,17}. Anthropometric measures of central fat has been proposed as a great additional criteria for monitoring overweight and obesity\textsuperscript{18-20}. Moreover, anthropometric measures of central fat maybe a reliable method to monitor early changes in body fat mass in adolescent swimmers\textsuperscript{14}.

There is little data on adherence to the MD and adolescent swimmers\textsuperscript{21}. In our knowledge, there is no studies linking the MD and anthropometric measures of central fat in adolescent competitive swimmers. The purposes of this study were: to assess the degree of adherence to the MD and its relationship with some anthropometric indices of central fat in competitive adolescent swimmers.

Material and method

Participants

A cross-sectional descriptive study was carried out. We selected 74 competitive adolescent swimmers aged between 11 and 16 y.o. from four local swimming clubs. We included swimmers with a minimum of three years of sport experience. The study was carried out in March 2017, 3 weeks after the main national and regional championships. The swimmers are semiprofessional and they usually have five or six swimming sessions per week. Normally in each session, the swimmers swam between 90 and 120 minutes (min) and covered a minimum of 3.000 meters (m). All swimmers participated voluntarily in the study and their legal guardian signed a written informed consent. The ethics committee of the University of Alicante granted ethical approval, according to the Declaration of Helsinki.

Experimental design

To assess the adherence to the MD, the swimmers completed the KIDMED questionnaire. The KIDMED questionnaire was developed by Serra-Majem et al.\textsuperscript{22} and revised to its Spanish version\textsuperscript{23}. The questionnaires were provided to each participant by one or more researchers and the guidelines were explained to all participants to ensure that the questionnaire was completed appropriately. The KIDMED questionnaire is composed of sixteen questions, of which, four affirmative questions have been assigned with a negative score of -1. While the rest have been assigned with a positive sign of +1. The results of the KIDMED questionnaire were classified, according to the KIDMED authors, into three levels: 8-12 (high) optimal Mediterranean diet; 4–7 (medium) improvement needed to adjust intake to Mediterranean patterns; 0-3 (poor) very low diet quality\textsuperscript{22-23}. Anthropometric data collection was carried out at the beginning of the afternoon swimming session. Participants were only wearing a swimsuit during anthropometric data collection. A II level anthropometrist accredited by the International Society for the Advancement of Kinanthropometry (ISAK) collected the measures according to the ISAK standards\textsuperscript{24}. The height, waist, and hip circumference was measured with a standard flexible metallic measuring tape. Body mass was recorded using an electronic scale (Tanita BH 420MA, Tanita Corporation, Japan). Body mass index (BMI) was determined using standard equations: BMI=\(\text{body mass (kg)/height}^2\) (m). The waist/hip ratio (WHr) was calculated as waist circumference divided by hip circumference and the waist/height ratio (WHeir) was calculated as waist circumference divided by height. To avoid subjective error, all measurements were assessed twice, and the relative mean values were used. In case of a discrepancy from 5% to 10% between the two measurements, a third was taken.

Data analysis

Data were grouped according to sex and age group. A group included younger swimmers (aged 11 - 13 years) and the other included older swimmers (aged 14 -16 years) according to the youth swimming categories of the Royal Spanish Swimming Federation. All data are presented as mean with standard deviation (SD) and confidence intervals were calculated (95%-CI). Each question of the KIDMED questionnaire was analyzed by age and sex, and the ORs and the combinations of them were calculated. Statistical analyses were performed using logistic regression adjusting for sex and age. For the latter analysis, the younger males group was the baseline. To assess the adherence to the MD a linear regression analysis was performed. At t-test was applied for differences between sexes and ages. Statistical analyses were performed using Statistical Package for the Social Sciences 18.0 software for Windows (IBM SPSS Software, Armonk, NY, USA) with statistical significance set at \(p \leq 0.05\).

Results

Adherence to the MD

The swimmers showed medium adherence to the MD. The mean KIDMED score was 7.62 ± 1.86. 2 swimmers (2.7%) showed a poor index.
Adherence to the Mediterranean diet, is there any relationship with main indices of central fat in adolescent competitive swimmers?

Table 1. Scores of the KIDMED questionnaire. Linear regression by age, sex and age x sex.

Measurements of the central fat

The physical and anthropometric characteristics of the competitive adolescent swimmers are shown in Table 3. All the anthropometric measurements were within the normal range for these ages. The swimmers showed healthy anthropometric values of central fat. As expected there were differences in body mass and height between sexes, although BMI values were not. There also were differences in waist circumference between sexes, although there were not in hip.

There were differences in WHipr between sexes. Whereas the female swimmers showed a significant lower WHipr compared to males (-0.028; CI 95%: -0.05 -0.01; p = 0.01). There was no correlation between WHipr and age or KIDMED score. There was no correlation between WHipr and age, BMI and sex, age or KIDMED score.

Discussion

The KIDMED scores of the swimmers were not correlated with the anthropometric measurements of central fat. Greater adherence to a Mediterranean diet should lead to a lower total and central fat in children and adolescents. Regardless of the degree of adherence to the MD, a high level of swimming would disguise the possible effects of an unhealthy or imbalanced diet. Based on our results, the adherence to the MD worsens with age. An explanation could be that older adolescents have some money to spend on food and entertainment without any parental control. The adolescent swimmers spend many hours out of the home to go to and back from the swimming training and they usually share “food time” after the swimming session. The possibility of adolescents to spend money on food out of the home does not lead to a healthy diet, and it could increase bad eating habits with higher intake of ultra-processed food and sweet beverages. Previous data regarding sex and adherence to the MD in adolescents are unclear. Our results showed that the female swimmers had a lower adherence to the MD than males ones. Moreover, it was observed that female swimmers had lower nutritional knowledge than male ones. We have reported that the girls consumed less fruit and legumes and there were only females who usually skip breakfast. Several studies have shown that women, especially adolescent ones, have a higher prevalence of eating disorders than men. Although swimming is not considered a high-risk sport regarding eating disorders, greater attention should be given to the nutritional behavior of the swimmers, especially female ones. Almost all the swimmers consumed a piece of fruit or fruit juice daily. We have expressed some concerns about the inclusion of fruit juice in the KIDMED questionnaire. The repeated inclusion of fruit juice in the diet may have negative effects. The percentage of intake of the second piece of fruit in the second answer was lower than the percentage recorded for the first one (see Table 1). Thus, the high percentage recorded of daily intake of fruit in the first answer could be a false “cognate” biased by fruit juice intake. The number of adolescent swimmers that consumed the second piece of fruit daily is alarming. We could deduce that few swimmers consume the recommended servings of fruit per day. The current dietary guidelines have been advocating for an increase of fruit intake instead of fruit juice. An increase of fruit intake in adolescent swimmers is strongly advisable. A possible alternative to improve the fruit intake and to substitute the fruit juice could be fruit smoothie intake. The fruit smoothie is well accepted by adolescents and it supplies water, fat, dietary fibre, vitamins, and antioxidants.

The coaches reported to us that there is no nutrition education at swimming clubs. Nutritional education appears to be an effective resource to improve Mediterranean nutritional habits in adolescent swimmers. Targets for such education should not be limited to swimmers but also include families, schools, and coaches. Several studies have shown that the coaches had inadequate sport nutritional knowledge. Furthermore, they often provide nutritional advice to their athletes, even though they are not competent to do so.

Studies have reported an unclear correlation between adherence to the MD, physical activity, and BMI values. Some studies have used the body mass index (BMI) to monitor fat component. Although the male and female swimmers showed differences in height and body mass, they had similar healthy BMI. Some studies have suggested that male and female swimmers could have the same BMI with different proportions of lean mass and fat mass. However, the results did not show any correlation between BMI and the adherence to the MD. We have some concerns about BMI, mainly because it does not provide any information about the distribution of body fat. The addition of measures of central fat to BMI should be considered as greater criteria for monitoring overweight and obesity. In the present study, all swimmers were semi-professional and they had a minimum of three years of sport experience. Many of them have been swimming since childhood. The results showed that the high level of swimming since childhood maintains weight and the BMI of both sexes in a healthy range.

The relationship between adherence to the MD and waist circumference is not clear. Waist circumference could reflect total body fat and fat distribution in children and adolescents. Accumulation of central fat is a negative factor in swimming because central fat increases the frontal surface of the body and increases the total drag force on a swimmer. In our study, the swimmers showed a low level of fatness and healthy values of waist circumference. To have low fatness indices with healthy waist circumference values could indicate a developed kick musculature, which is the key factor for high performance in swimming. However, some anthropometric measurements of central fat could be used as early predictive measurements to assess changes in body fat at least in young swimmers.

The female swimmers showed a significant lower WHipr than males. A low level of WHipr in women is correlated with a low risk of cardiovascular disease, diabetes, and hypertension.

Sedentary behaviors in adolescents commonly lead to overweight and obesity. Consistent with previous studies, our study has observed that all swimmers have healthy values in all anthropometric measurements and they did not show any accumulation of total or central fat. Thus, as expected an elevated level of swimming activity prevents the accumulation of total and central fat. Despite there was no correlation between adherence to the MD and the main indices of central fat, there are reasons related to health to improve healthy eating habits of adolescent swimmers.
Limitations of the study
The cross-sectional design of the current study has some limitations. The study is a “status study” and the results are a picture indicating what is being done. The conclusions could be used as valuable indications to be taken into account for future research. The size of the sample of the study is limited. However, to our knowledge, the number of participants is higher compared to other studies. The study did not measure the relationship between the degree of adherence to the MD and some anthropometric indices of central fat with the performance in competitive adolescent swimmers.

Conclusions
There was no correlation between adherence to the MD and the main indices of central fat in competitive adolescent swimmers. Regardless of the medium adherence to the MD, the elevated swimming activity had a protective role to prevent the accumulation of central fat.

Conflict of interests
This research did not receive any grant from funding agencies in the public, commercial, or non-profit sectors. The authors have disclosed that they have no relationships with, or financial interest in, any commercial companies. Cesare Altavilla was a coach of 10 of the swimmers, who participated in the study.
